Disclosure Regulation, Stock Liquidity, and International Policy Diffusion

Online Appendix

26 October 2026

This Online Appendix defines the variables and reports country controls, alternative trading measures, event dynamics, portfolio timing, conditional learning, cross sections and model support. The main paper's five liquidity pooling models form the primary comparison. Secondary country–cohort tests use their stated samples and change windows. Complete coefficient matrices retain every estimated, unestimated and unstable specification.

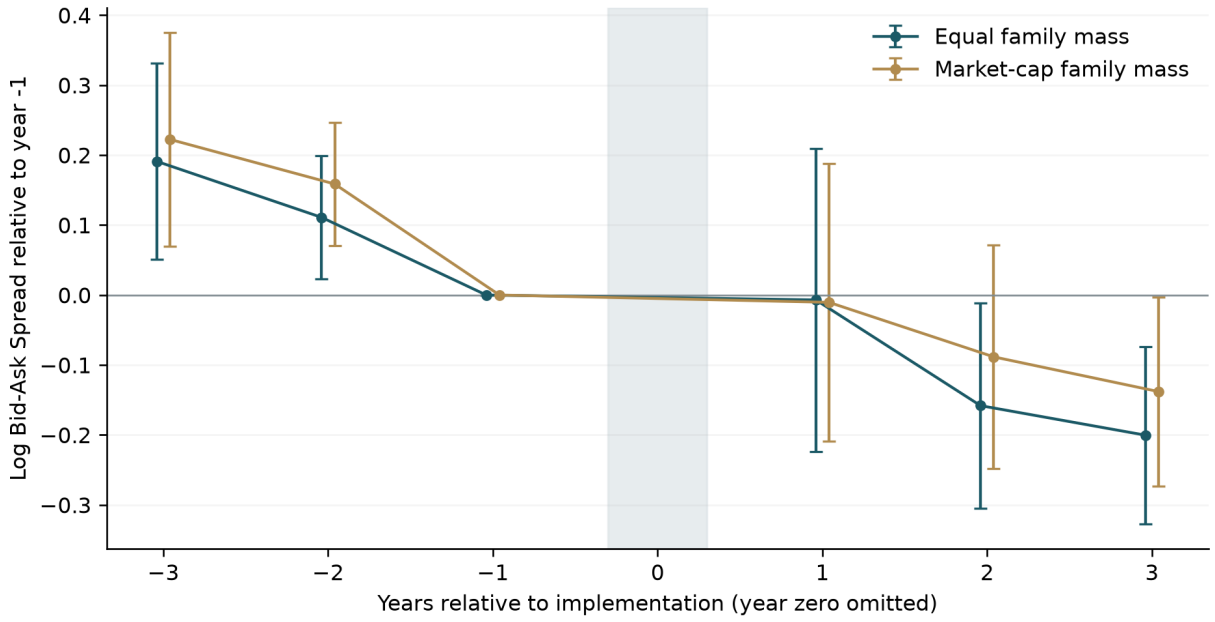

Figure A1: Stock-liquidity dynamics on the primary stacked sample

This figure reports event-time coefficients and pointwise country-cluster 95% intervals from Table A4. The sample holds companies fixed across years $-3, -2, -1, 1, 2, 3$. Year -1 is the reference; year zero is omitted. The two series use equal and market-cap family objective mass on the same five-family, 46-country sample. Higher log Bid-Ask Spread indicates lower stock liquidity.

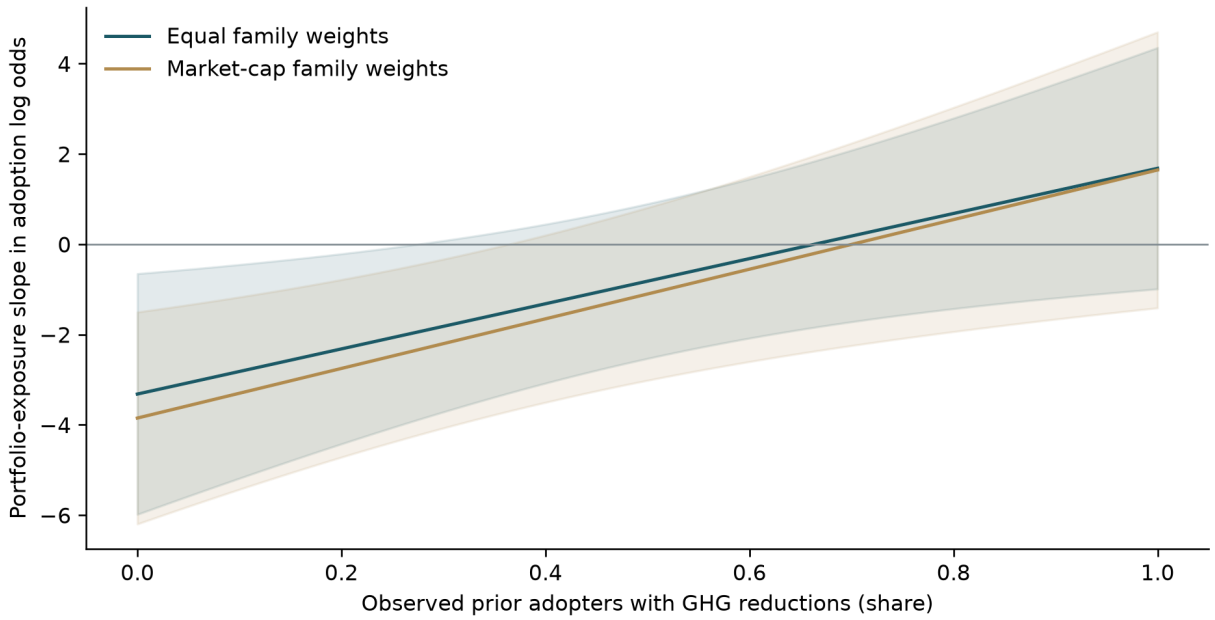

Figure A2: Foreign emissions reductions and the portfolio-exposure slope

This figure reports the slope $\widehat{\theta}_P + \widehat{\theta}_{P\times H} H$ from Table 4's environmental-learning logit models and conditional 95% intervals using the full coefficient covariance. The horizontal axis is the observed success share between its 10th and 90th sample percentiles. The vertical axis is the adoption log-odds slope per standardized portfolio exposure, rather than a probability change. The two fits use 138 risk-year observations in 18 countries and five public families. Both primitive terms and their interaction, Family FE, Year FE and country controls are included. The plot conditions on the model and observed support.

Table A1: Variable definitions and data construction

Manuscript variable	(1) Source and units	(2) Reference period and exact construction
Log Bid-Ask Spread	Datastream; annual log units	Company annual median of $2(Ask-Bid)/(Ask+Bid)$, requiring 120 spread days and a positive annual spread no greater than one before within-year 1st/99th-percentile trimming; log afterward. Country mean uses the fixed largest positive-cap share line per vendor company at $g-1$, complete over all six window years; at least 30 companies.
Log price impact	Datastream; annual log units	Company annual median $\lvert r\rvert/(USD\ volume)$, multiplied by 10^8; at least 120 valid impact days and more than one distinct price. Positive annual values receive within-year 1st/99th-percentile trimming before logging. Country aggregation uses the same complete companies as spread.
Zero-return share	Datastream; fraction	Observed valid daily returns equal to zero divided by observed valid return days; at least 120 valid return days and more than one distinct price. This denominator is observed returns, not all potential exchange trading days. No additional annual trimming.
Illiquidity index	Datastream; standardized average	Equal mean of log Bid-Ask Spread, log price impact and zero-return share, each standardized using complete, positive-cap, largest-share-line company observations in 2000. Index weights are 1/3 each; calibration means and sample SD (denominator $n-1$) are supplied. Higher values mean less stock liquidity.
Public disclosure × Post	Policy documents; 0/1	Adopting country in the relevant family–implementation-year stack, interacted with years $g+1$ to $g+3$. Pre-reform years are $g-3$ to $g-1$; year g is omitted. Controls have a documented implementation after $g+3$. The date is a reviewed legal/reporting phase, not an observed issuer filing date.
First implementation	Policy documents; 0/1 risk year	One in first recorded country–family implementation year G, zero in documented years before G. Risk panel covers 2002–2025 and stops at G. Unknown histories and outside-home-regime bank geographic controls do not become never-adopting risk countries. This is first documented implementation within the compiled chronology.
Portfolio exposure (P)	IMF PIP; fraction at $t-1$	Annual total portfolio asset positions; holder and counterpart Total economy, Total investment, USD. Positive observed non-self positions only. Sum positions in partners adopted by $t-1$ divided by sum positions in partners with documented policy histories. Require known-history mass / all observed positive mass ≥ 0.50. Alternative coverage 0.80, positions at $t-2$, and fixed-2001 shares are supplied; fixed 2001 starts in 2003.
Liquidity-success share (S)	Policy dates and Datastream; fraction	For known portfolio partners implemented by $t-2$, observed success equals one if mean log Bid-Ask Spread falls from $t-2$ to $t-1$ for the same pre-selected companies (at least 30). S is the unweighted fraction of observed eligible donors with a fall. Observed donors must cover at least 80% of eligible-adopter portfolio mass. With no eligible adopters, the signal is zero; missing outcomes are not imputed.
Liquidity-success exposure	IMF PIP and Datastream; fraction	Sum normalized known-partner portfolio weights for observed eligible donors with a spread fall. Eligible donors and 80% outcome-coverage rule match S. Differs from S because portfolio size weights the successful donors.
Liquidity magnitude exposure	IMF PIP and Datastream; weighted log difference	Sum known-partner portfolio weights times $-\Delta\log(Spread)$ from $t-2$ to $t-1$ among observed donors implemented by $t-2$. The same coverage and no-imputation rules apply.
Liquidity threshold exposure	IMF PIP and Datastream; fraction	Sum portfolio weights for observed eligible donors with improvement above the same-year median improvement among documented prior adopters excluding the focal country. Require at least three observed donors for the threshold. Negative or zero median improvements do not imply a causal policy success.

Continued on next page

Manuscript variable	(1) Source and units	(2) Reference period and exact construction
Domestic liquidity (D)	Datastream; negative log Bid-Ask Spread at $t-1$	Negative mean log Bid-Ask Spread in the fixed-company adjacent-year sample ending in $t-1$; a larger value means a more liquid domestic market. Used with P, S, all three pairwise products and the $P \times S \times D$ product.
GHG-reduction share (H)	UNFCCC and policy dates; fraction	Unweighted fraction of observed eligible prior adopters whose aggregate GHG emissions excluding LULUCF/LUCF fall between consecutive years $t-2$ and $t-1$. Emissions are observed source values; no interpolation or forward/backward filling. Eligible-donor and 80% observed-mass rules match S.
Domestic GHG (Q)	UNFCCC; log kt CO_2 equivalent at $t-1$	Natural log of positive observed aggregate emissions excluding LULUCF/LUCF in the preceding year. Original files use kt or Gg CO_2 equivalent; 1 Gg equals 1 kt. Used in $P \times H \times Q$ specifications with all lower-order terms.
Nearest larger adoption	Geographic network, World Bank GDP and policy dates; 0/1	Choose the nearest country with GDP in 2000 above focal GDP among the ten ranked geographic peers. One if that fixed peer has documented implementation by $t-1$, zero if its documented date is later. Missing if no valid larger peer/history exists; no smaller-country substitute.
Recent / older leader adoption	Same sources; 0/1	Recent equals one if the fixed larger peer implements in $t-1$; older equals one if implementation is before $t-1$. Both are zero when its documented implementation is later. Missing larger-peer history remains missing.
Trade competition	IMF trade network and policy dates; fraction	Fraction of documented prior adopters among five peers with the most similar export-destination patterns in 2000. Similarity is the correlation of destination shares with at least 20 jointly observed destinations. At least three peers need documented policy histories. Unknown peer histories are excluded from the denominator, not coded zero.
GDP-growth learning	CEPII geography, policy dates and World Bank; 0/1	Select ten nearest countries by capital-city distance from the family-specific documented-history universe, excluding the focal country. Require all ten peer histories and at least 80% prior-year growth coverage within each available adopter/nonadopter group. One if adopter median growth exceeds nonadopter median growth. No prior adopters gives zero; if all ten are prior adopters, compare their median with focal growth. Fewer than ten documented peers gives missing.
Language-peer adoption	Official-language network and policy dates; fraction	Known prior adopters divided by peers with documented histories among countries sharing an official language; require at least three known peers. It is a language proximity measure, not the composite Berry administrative-distance index.
External financial dependence	World Bank; percentage points of GDP	100 times prior-year use of IMF credit and SDR allocations plus net official development assistance, divided by prior nominal GDP. This follows the supplied imf-credit-and-SDR series and net-aid series; no IMF conditionality is inferred. Missing components remain missing. Continuous value is standardized for model estimation.
Cross-listed firm share	Country market aggregation; fraction at $t-1$	Number of sampled cross-listed firms divided by total sampled firms in the preceding year. The ratio is verified against the source numerator and denominator. Measures general foreign-listing familiarity; does not identify the host-country policy of each issuer.
Country controls	World Bank; preceding year	Natural log real GDP per capita, real GDP growth in percentage points, and trade/GDP in percentage points, each lagged one calendar year. No zero filling or interpolation is added. Revisions are the source vintage, not real-time policy-information releases.
Primitive standardization	Estimation sample; standard deviations	Each continuous primitive is centred by its unweighted model-sample mean and divided by population SD (ddof=0). Binary 0/1 variables remain unscaled. The same sample and standardization are used for paired equal/cap weights. Exact means and SD are supplied for every fit.

Continued on next page

Manuscript variable	(1) Source and units	(2) Reference period and exact construction
Double and triple interactions	Constructed; products of standardized primitives	Double uses P, success share and their product. Triple uses P, success, domestic capacity, all three pairwise products and the triple product. The product itself is not standardized a second time. Every lower-order term is included.
GDP country weights	World Bank; pre-reform GDP	Positive GDP in $g-1$ is fixed within each country–stack. Country weights are normalized to unit mass within each cohort and year block; cohort mass is proportional to adopting-country prior GDP. Country-by-stack and year-by-stack means are removed with these weights.
Equal / cap family objective mass	Policy and Datastream; normalized weights	Equal mass is 1/F. Cap mass sums sampled positive company market values in $g-1$ across supported adopting country–cohorts, then normalizes across families. Stacked slopes also reflect residual treatment information; explicit family averages apply these weights to family coefficients directly.
GLS family weights	Country-score covariance; weights sum to one	With family coefficients b and shared-country covariance V, $w = V^{-1}1/(1'V^{-1}1)$ and coefficient $w'b$. Report covariance condition/rank and estimated weight concentration. Standard errors condition on estimated weights; unrestricted GLS may have negative weights in other specifications.
Diffusion family weights	Policy and country market data; normalized mass	Equal-family likelihood mass assigns each supported family equal total weight. Cap mass sums observed country sampled-company capitalization in the year before each documented implementation with at least 30 company records. Each model normalizes supported-family masses and divides by family risk-row counts.
Secondary Δ outcomes	Country–cohort liquidity; changes	For cross sections and matching, Δ is the fixed-company country mean in $g+1$ minus its level in $g-1$. GDP weights pool cohort estimates, then equal or pre-policy cap weights pool families. These are secondary country–cohort samples, distinct from the six-year stacked sample.
Cross-sectional moderators	Datastream and World Bank; $g-1$	Prior own liquidity, regulatory quality, market cap/GDP, log GDP per capita and trade/GDP. Each is centred and scaled by the unweighted eligible-country SD within cohort. Regression includes Treat, moderator and their product; at least two treated and six controls, full rank and three residual df.
Matching weights	Pre-reform country characteristics; nearest neighbours	Three nearest documented controls per adopter by Mahalanobis distance on $g-1$ log income, trade/GDP and all three liquidity levels, with replacement. Covariance adds $10^{-6}\,trace(V)/p$ on the diagonal. No outcome-selected caliper. Pooling and country influence follow the secondary cohort design.

This table reports definitions for all primary and secondary outcomes, treatment indicators, diffusion regressors, interactions, controls and analytical weights. Sources, units, timing, transformations, missing-data rules and alternative constructions are stated for replication. Model-specific standardizations, memberships and full coefficient matrices accompany the paper. No regression is estimated in this table.

Table A2: Stock liquidity with country controls

Variable	(1) Stacked Equal mass	(2) Stacked Cap mass	(3) Family average Equal	(4) Family average Cap	(5) GLS Common effect
Public disclosure × Post	-0.187***	-0.183***	-0.147**	-0.160**	-0.157***
	(0.048)	(0.057)	(0.065)	(0.075)	(0.042)
Countries	45	45	45	45	45
Country–stack–years	990	990	990	990	990
Pre-reform lead-test p	0.032	0.001	0.021	$< .001$	0.178
Country FE × stack	X	X	X	X	X
Year FE × stack	X	X	X	X	X
Lagged country controls	X	X	X	X	X

This table reports the five pooled liquidity specifications with country controls. The dependent variable is country–stack–year mean company log Bid-Ask Spread, in log units. Columns match the five pooling methods in main Table 3; each adds prior-calendar-year log real GDP per capita, GDP growth and trade/GDP to its level regression. The control-complete sample has five families; observations and countries are reported by column. The same three pre-reform years and years 1–3 after implementation are used, with Country FE × stack and Year FE × stack. Data are official policy histories, Datastream and World Bank country series. Country-cluster score covariance preserves repeated countries across all fitted stacks; GLS errors condition on its estimated covariance weights. All five grid-wide adjusted p-values equal 1.000. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A3: Pooled public-disclosure estimates across liquidity measures

Variable	(1) Stacked Equal mass	(2) Stacked Cap mass	(3) Family average Equal	(4) Family average Cap	(5) GLS Common effect
Panel A. Log Bid-Ask Spread					
Public disclosure × Post	-0.223***	-0.206***	-0.199***	-0.199***	-0.238***
	(0.048)	(0.058)	(0.058)	(0.066)	(0.025)
Grid-adjusted p	0.149	1.000	1.000	1.000	$< .001$
Panel B. Log price impact					
Public disclosure × Post	-0.105	-0.134	-0.029	-0.081	-0.132**
	(0.101)	(0.112)	(0.081)	(0.099)	(0.050)
Grid-adjusted p	1.000	1.000	1.000	1.000	1.000
Panel C. Zero-return share					
Public disclosure × Post	-0.008**	-0.007**	-0.007**	-0.007*	-0.009***
	(0.003)	(0.003)	(0.003)	(0.004)	(0.002)
Grid-adjusted p	1.000	1.000	1.000	1.000	1.000
Panel D. Illiquidity index					
Public disclosure × Post	-0.098***	-0.095***	-0.081***	-0.086***	-0.109***
	(0.018)	(0.021)	(0.020)	(0.022)	(0.014)
Grid-adjusted p	0.011	0.181	0.801	1.000	$< .001$
Country–stack–years	1,002	1,002	1,002	1,002	1,002
Country FE × stack	X	X	X	X	X
Year FE × stack	X	X	X	X	X

This table reports all four liquidity outcomes on the common primary fixed-company sample. The dependent variable is log Bid-Ask Spread in Panel A, log price impact in Panel B, zero-return share (fraction) in Panel C, and the standardized equal-weight illiquidity index in Panel D. Columns are the five main pooling methods. Each uses 1,002 country–stack–years, 46 countries, five families, GDP country weights, three pre-reform years and years 1–3 after implementation. Country FE × stack and Year FE × stack are included; no time-varying controls enter these columns. Data are Datastream and official policy documents. Country-cluster score errors preserve shared-country covariance across stacks and families; GLS weights are outcome-specific and inference is conditional on them. Adjusted p covers the 5,184-cell matrix. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A4: Stock-liquidity dynamics around public-disclosure implementation

Event indicator	(1) Stacked equal mass	(2) Stacked cap mass
Treat × year -3	0.191***	0.222***
	(0.070)	(0.076)
Treat × year -2	0.111**	0.159***
	(0.044)	(0.044)
Treat × year 1	-0.007	-0.010
	(0.108)	(0.098)
Treat × year 2	-0.158**	-0.088
	(0.073)	(0.079)
Treat × year 3	-0.200***	-0.138**
	(0.063)	(0.067)
Joint pre-reform lead-test p	0.017	0.001
Country FE × stack	X	X
Year FE × stack	X	X

This table reports event-time coefficients from the primary stacked sample. The dependent variable is country–stack–year mean log Bid-Ask Spread, in log units. Each event indicator interacts adopting-country status with the specified year relative to implementation; year -1 is the omitted reference and year zero is excluded. Columns (1)–(2) use equal or cap family objective mass. The 1,002 observations, 46 countries and five families are fixed across event times. Country FE × stack and Year FE × stack are included; GDP sets country weights. Data are Datastream and official phase histories. Country-cluster scores provide coefficient errors; the joint lead test uses the asymptotic country-cluster Wald statistic for years -3 and -2. Nonrejection of a lead test is not proof of parallel trends. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A5: Stock-liquidity estimates across trimming, timing and windows

Post starts 1; 3 pre and post years	5	-0.215***	-0.193***
		(0.049)	(0.058)

This table reports stated alternative stacked liquidity specifications. The dependent variable is country–stack–year mean log Bid-Ask Spread, in log units. Columns (2)–(3) use equal or cap family objective mass; column (1) reports supported families. Each row uses the stated post-policy start and equal counts of pre and post years; companies remain fixed over that full window. Panels show no annual trimming, 1st/99th-percentile trimming and 2.5th/97.5th-percentile trimming of positive screened company annual spread/impact measures before logging. The support changes across windows; the accompanying matrix reports every row-specific country and observation count. Country FE $\times$ stack and Year FE $\times$ stack are included, without time-varying controls. Sources are official policy dates and Datastream. Country score covariance retains repeated countries; all matrix p-values and 5,184-cell Holm adjustments accompany the data. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A6: Portfolio exposure and learning: source coverage and timing

Construction	(1) Equal family weights	(2) Cap family weights
Panel A. Portfolio exposure

Observations / countries	111 / 16	111 / 16
Fixed 2001 positions	0.842	1.481*
	(0.527)	(0.700)
Observations / countries	180 / 15	180 / 15
Prior-year positions; 80% history	–	–
Observations / countries	0 / 0	0 / 0

This table reports exposure and learning regressions under alternative portfolio-data constructions. The dependent variable is First implementation, a binary country–family risk-year outcome in a discrete-time logit. Panel A reports portfolio exposure; Panels B and C report its interaction with observed foreign liquidity success or GHG reductions, with all corresponding primitive terms retained. Rows vary position timing, fixed-2001 network weights and minimum observed policy-history coverage; columns vary family weights. Row-specific sample counts are reported; failed or insufficiently supported fits show a dash, with the reason in the model ledger. Family FE, Year FE and lagged country controls enter all fitted specifications. Continuous primitive regressors and controls are standardized on each specification sample; binary variables retain 0/1 units. Products use the standardized primitives and include all lower-order terms. Country controls are prior-year log GDP per capita, GDP growth and trade/GDP. Data are the official policy register, IMF portfolio assets, Datastream liquidity and World Bank macro series. Country-cluster sandwich errors use finite-sample corrections and t critical values with countries minus one degrees of freedom. The full 1,024-attempt focal correction is supplied with every coefficient. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A7: Conditional learning and domestic capacity

Variable	(1) Equal family weights	(2) Cap family weights
Panel A. Domestic liquidity		
P	0.117	0.080
	(0.081)	(0.103)
S	-0.004	-0.013
	(0.031)	(0.040)

Panel B. Domestic GHG		
P	–	–
H	–	–
Q	–	–
P × H	–	–
P × Q	–	–
H × Q	–	–
P × H × Q	–	–
Observations	222	222
Countries	12	12
Disclosure families	6	6
Implementation events	11	11
Country FE × family		
Family FE × year		
Lagged country controls		

This table reports full triple-interaction learning specifications. The dependent variable is First implementation, in probability units in these linear probability models. Panel A combines standardized portfolio exposure *P*, observed foreign liquidity-success share *S* and domestic liquidity *D*; Panel B combines *P*, GHG-reduction share *H* and domestic log emissions *Q*. Every primitive, pairwise interaction and triple product is included. Columns use paired equal/cap family weights. Model-specific observations, countries, families and events are reported; the GHG primary sample has fewer than the required 15 countries and its unestimated coefficients are dashes. Country FE × family, Family FE × year and lagged income, growth and trade/GDP enter the fitted models. Continuous primitive regressors and controls are standardized on each specification sample; binary variables retain 0/1 units. Products use the standardized primitives and include all lower-order terms. Country controls are prior-year log GDP per capita, GDP growth and trade/GDP. Data are the official policy register, IMF portfolio assets, Datastream liquidity and World Bank macro series. Country-cluster sandwich errors use finite-sample corrections and *t* critical values with countries minus one degrees of freedom. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A8: Cross-sectional variation in secondary liquidity comparisons

Interaction coefficient	(1) Equal family weights	(2) Cap family weights
Panel A. Pre-reform illiquidity		
Δ Log Bid-Ask Spread: Treat × moderator	-0.065	-0.451*

Interaction coefficient	(1) Equal family weights	(2) Cap family weights
Panel D. Income		
Δ Log Bid-Ask Spread: Treat × moderator	0.391	0.573
	(0.462)	(0.770)
Country–cohort records / families	69 / 2	69 / 2
Δ Log price impact: Treat × moderator	-0.603***	-0.429*
	(0.146)	(0.241)
Country–cohort records / families	69 / 2	69 / 2
Δ Zero-return share: Treat × moderator	-0.014	-0.008
	(0.010)	(0.014)
Country–cohort records / families	69 / 2	69 / 2
Panel E. Trade openness		
Δ Log Bid-Ask Spread: Treat × moderator	0.532**	0.261
	(0.210)	(0.254)
Country–cohort records / families	68 / 2	68 / 2
Δ Log price impact: Treat × moderator	5.608***	1.456***
	(0.065)	(0.117)
Country–cohort records / families	68 / 2	68 / 2
Δ Zero-return share: Treat × moderator	0.158***	0.046***
	(0.005)	(0.008)
Country–cohort records / families	68 / 2	68 / 2

This table reports treatment-by-moderator coefficients from secondary country–cohort comparisons. The dependent variable is Δ log Bid-Ask Spread, Δ log price impact or Δ zero-return share, with the Δ defined as $g+1$ minus $g-1$ on fixed company observations. Panels map to prior own illiquidity, regulatory quality, market cap/GDP, log income and trade/GDP, measured at $g-1$, centred and divided by the eligible-country SD within cohort. Treat and moderator main effects and cohort intercepts are included; there are no Country FE in these country-change regressions. Equal/cap columns pool the same supported family estimates using GDP country weights. Each moderator supports two public families; record counts are shown. Sources are official policy records, Datastream and World Bank series. Shared-country influence contributions produce conditional country errors; exact 108-comparison Holm adjustments accompany the supplied secondary results. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A9: Matched-country secondary liquidity comparisons

Variable	(1) Equal Unmatched	(2) Equal Matched	(3) Cap Unmatched	(4) Cap Matched
Panel A. Δ log Bid-Ask Spread				
Treat	-0.073	-0.126*	-0.074	-0.115*
	(0.061)	(0.067)	(0.059)	(0.065)
Country–cohort records	132	100	132	100
Disclosure families	4	4	4	4
Nearest-three matching		X		X
Panel B. Δ log price impact				
Treat	0.056	-0.052	0.048	-0.035
	(0.109)	(0.114)	(0.097)	(0.101)
Country–cohort records	132	100	132	100
Disclosure families	4	4	4	4
Nearest-three matching		X		X
Panel C. Δ zero-return share				
Treat	-0.002	-0.004	-0.001	-0.003
	(0.006)	(0.006)	(0.006)	(0.006)
Country–cohort records	132	100	132	100
Disclosure families	4	4	4	4
Nearest-three matching		X		X

This table reports unmatched and matched coefficients on the secondary matching-eligible sample. The dependent variable is Δ log Bid-Ask Spread in Panel A, Δ log impact in Panel B and Δ zero-return share in Panel C, measured from $g-1$ to $g+1$ for fixed companies. Treat identifies documented adopting countries. Columns (1)–(2) use equal family weights and (3)–(4) cap family weights, with GDP country weights within family. Matching selects three nearest documented controls per adopter with replacement using pre-reform income, trade/GDP and all three liquidity levels; exact balance statistics accompany the data. Four public families are supported and country–cohort record counts are reported. Cohort intercepts enter the country-change regressions; Country FE do not. Data are policy records, Datastream and World Bank series. Country influence errors are conditional on the selected matches and aggregate repeated countries across fits; extension-wide adjusted p-values are supplied. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A10: Copying larger economies: recent and older implementation

Variable	(1) Equal family weights	(2) Cap family weights
Panel A. Independent national choices		
Nearest larger peer: recent adoption	–	–
Nearest larger peer: older adoption	–	–
Observations	164	164
Countries	12	12
Disclosure families	6	6
Implementation events	20	20
Family FE		
Year FE		
Lagged country controls		
Panel B. All documented implementations		
Nearest larger peer: recent adoption	0.118	-0.742
	(0.803)	(1.174)
Nearest larger peer: older adoption	-0.917	-1.905**
	(0.614)	(0.718)
Observations	988	988
Countries	33	33
Disclosure families	8	8
Implementation events	115	115
Family FE	X	X
Year FE	X	X
Lagged country controls	X	X

This table reports discrete-time logit estimates separating recent and older implementation by a fixed larger geographic peer. The dependent variable is First implementation, a 0/1 country–family risk-year indicator. Recent means the peer implemented in $t-1$ and older means implementation before $t-1$. The peer is selected among the ten geographic neighbours using GDP in 2000, and is fixed before model estimation. Panel A uses independent national choices and Panel B includes documented coordinated implementations; paired columns use equal/cap family weights. Sample counts are reported. The independent-choice sample has only 12 countries and is unestimated under the 15-country rule. Family FE, Year FE and lagged income, growth and trade/GDP enter the fitted models. Sources are policy documents, the geographic network and World Bank GDP. Country-cluster sandwich errors and t critical values use countries minus one df; all tested cells remain in the 1,024-comparison adjustment. Standard errors are in parentheses on the separate row below each coefficient. ***, ** and * denote two-sided significance at 1%, 5% and 10%, respectively.

Table A11: Diffusion model coverage and estimation status

Status	(1) Specifications	(2) Observation range	(3) Country range
estimated	422	60–3334	15–73
estimation failed	2	123–123	17–17
insufficient sample support	144	0–310	0–30
rank or absorbed outcome	22	55–1245	22–41
unstable logit	98	51–2644	15–73

This table reports the complete prespecified diffusion model ledger. It covers 16 theory-defined models, both family weights, public and combined public/confidential scopes, independent and all-documented choices, two estimators and the stated portfolio timing/coverage alternatives, yielding 688 specifications and 1,024 focal coefficient attempts. Estimates require at least 50 observations, 15 countries, ten events and ten nonevents, full rank, and positive residual and cluster variance. Family/year groups without outcome variation are iteratively excluded in the logit support calculation. Unstable or failed fits are preserved with their source samples and diagnostics; their tests enter Holm adjustment as $p = 1$. The complete coefficient and membership files accompany the paper. No additional regression is estimated in this table.
